Intellectual Property Rights

IPRs essential or potentially essential to the present document may have been declared to ETSI. The information pertaining to these essential IPRs, if any, is publicly available for **ETSI members and non-members**, and can be found in ETSI SR 000 314: *"Intellectual Property Rights (IPRs); Essential, or potentially Essential, IPRs notified to ETSI in respect of ETSI standards"*, which is available from the ETSI Secretariat. Latest updates are available on the ETSI Web server (http://ipr.etsi.org).

Pursuant to the ETSI IPR Policy, no investigation, including IPR searches, has been carried out by ETSI. No guarantee can be given as to the existence of other IPRs not referenced in ETSI SR 000 314 (or the updates on the ETSI Web server) which are, or may be, or may become, essential to the present document.

Foreword

This European Standard (EN) has been produced by ETSI Technical Committee Environmental Engineering (EE).

The present document is

National transposition dates	
Date of adoption of this EN:	1 October 2014
Date of latest announcement of this EN (doa):	31 January 2015
Date of latest publication of new National Standard or endorsement of this EN (dop/e):	31 July 2015
Date of withdrawal of any conflicting National Standard (dow):	31 July 2015

Modal verbs terminology

In the present document "**shall**", "**shall not**", "**should**", "**should not**", "**may**", "**need not**", "**will**", "**will not**", "**can**" and "**cannot**" are to be interpreted as described in clause 3.2 of the ETSI Drafting Rules (Verbal forms for the expression of provisions).

"must" and "must not" are NOT allowed in ETSI deliverables except when used in direct citation.

Introduction

The present document specifies a metric for the assessment of energy efficiency of computer servers using reliable, accurate and reproducible measurement methods, which take into account the recognised state of the art.

The specification formalizes the metrics representing a single figure of merit of a single computer server representing the relative efficiency and power impact at a data centre level of deployment. The metric is targeted for use as a tool in the selection process of servers to be provisioned for a data centre.

Editors NOTE: still need to elaborate on this here

The present document is based upon the Server Efficiency Rating Tool (SERT)™ of the Standard Performance Evaluation Corporation (SPEC) and takes into account:

- the Ecodesign Technical Assistance Study on Standards for Lot 9 Enterprise Servers and Enterprise Data Storage
- energy efficiency KPIs standardisation in ISO/IEC JTC/1 SC/39 and CLC TC 215;
- activity related to deployed power by The Green Grid,;
- Energy Star.

This work item defines energy efficiency metrics and measurement methodology for server equipment under standardisation Mandate M/462 of the European Commission. The document does not address home servers and small servers under the Mandate M/545.

1 Scope

The present document specifies a metric for the assessment of energy efficiency of computer servers using reliable, accurate and reproducible measurement methods, which take into account the recognised state of the art.

The metric applies to general purpose 1 and 2 socket computer servers, with their own dedicated power supply, provisioned for use within a data centre of which the data processing requirement exceeds the use of a single server.

The metric applies to a computer server product family, including type and count of CPU, memory, storage, power supplies, cooling (e.g. fans) and any other add-on hardware expected to be present when deployed.

The metric applies to the following types of rack-mounted or pedestal form-factor servers:

- blade server with no more than four processor sockets per blade;
- multi-node with no more than four processor sockets.

The present document defines:

- an energy efficiency metric to support procurement requirements;
- requirements for equipment to perform the measurements and analysis;
- requirements for the measurement process;
- requirements for the management of the KPI calculation;
- operation or run rules to configure, execute, and monitor the testing;
- documentation and reporting requirements;
- a validation process for the metric to data centre level impact.

The present document is not applicable to:

- fully fault tolerant servers;
- High Performance Computing systems;
- hyper-converged servers;
- large servers;
- network equipment;
- network servers;
- server appliances;
- storage products including blade storage;
- storage servers.

NOTE: Products whose feature set and intended operation are not addressed by active mode testing parameters are excluded from this evaluation method. The above list shows products that are excluded from SERT efficiency evaluations.

2 References

References are either specific (identified by date of publication and/or edition number or version number) or non-specific.For specific references,only the cited version applies. For non-specific references, the latest version of the referenced document (including any amendments) applies.

Referenced documents which are not found to be publicly available in the expected location might be found at http://docbox.etsi.org/Reference.

NOTE: While any hyperlinks included in this clause were valid at the time of publication, ETSI cannot guarantee their long term validity.

Editor NOTE: How much can we reference from SPEC?

3 Definitions, symbols and abbreviations

Definitions and abbreviations extracted from ETSI deliverables can be useful when drafting documents and can be consulted via the ***Terms and Definitions Interactive Database (TEDDI) (http://webapp.etsi.org/Teddi/).***

3.1 Definitions

For the purposes of the present document, the following terms and definitions apply:

active state: operational state of a computer server in which the computer server is carrying out work in response to prior or concurrent external requests (e.g., instruction over the network) and includes both (1) active processing and (2) data seeking/retrieval from memory, cache, or internal/external storage while awaiting further input over the network

auxiliary processing accelerator: computing expansion add-in card installed in general-purpose add-in expansion slots (e.g. GPGPUs installed in a PCI slot)

Editors NOTE; needs update - not just a card

blade chassis: enclosure that contains shared resources for the operation of blade servers, blade storage, and other blade form-factor devices. Shared resources provided by a chassis may include power supplies, data storage, and hardware for dc power distribution, thermal management, system management, and network services.

blade server: computer server, designed for use in a blade chassis, that is a high-density device and functions as an independent computer server and includes at least one processor and system memory, but is dependent upon shared blade chassis resources (e.g. power supplies, cooling) for operation.

NOTE to entry: A processor or memory module that is intended to scale up a standalone server is not considered a blade server.

> **multi-bay blade server:** blade server requiring more than one bay for installation in a blade chassis
>
> **single-wide blade Server:** blade server requiring the width of a standard blade server bay
>
> **double-wide blade server:** blade server requiring twice the width of a standard blade server bay
>
> **half-height blade server:** blade server requiring one half the height of a standard blade server bay
>
> **quarter-height blade server:** blade server requiring one quarter the height of a standard server bay
>
> **multi-node blade server:** blade server which has multiple nodes
>
> NOTE to entry: The blade server itself is hot swappable, but the individual nodes are not.

blade storage: storage device that is designed for use in a blade chassis and that is dependent upon shared blade chassis resources (e.g., power supplies, cooling) for operation

blade system: system comprised of a blade chassis and one or more removable blade servers and/or other units (e.g. blade storage, blade network equipment) which provide a scalable means for combining multiple blade server or storage units in a single enclosure, and are designed to allow service technicians to easily add or replace (hot-swap) blades in the field

NOTE 1 to entry: HPC systems feature a large number of clustered homogeneous nodes often featuring high speed inter-processing interconnects as well as large memory capability and bandwidth.

NOTE 2 to entry: HPC systems may be purposely built, or assembled from more commonly available computer servers.

buffered DDR channel: channel or memory port connecting a memory controller to a defined number of memory devices (e.g. DIMMs) in a computer server

NOTE to entry: A typical computer server may contain multiple Memory Controllers, which may in turn support one or more Buffered DDR Channels. As such, each Buffered DDR Channel serves only a fraction of the total addressable memory space in a computer server.

computer server: computer that provides services and manages networked resources for client devices (e.g., desktop computers, notebook computers, thin clients, wireless devices, Personal Digital Assistants, Internet Protocol telephones, other computer servers, or other network devices).

NOTE 1 to entry: A computer server is sold through enterprise channels for use in data centers and office/corporate environments.

NOTE 2 to entry: A computer server is primarily accessed via network connections, versus directly-connected user input devices such as a keyboard or mouse.

direct current server: computer server that is designed solely to operate on a dierct current (d.c.) power source

dual-node server: common multi-node server configuration consisting of two server nodes

hyper-converged server: highly integrated enterprise device which contains the same components as a computer server in addition to the features of a network server and storage server

fully fault tolerant server: computer server that is designed with complete hardware redundancy, in which every computing component is replicated between two nodes running identical and concurrent workloads (i.e. if one node fails or needs repair, the second node can run the workload alone to avoid downtime) and that uses two systems to simultaneously and repetitively run a single workload for continuous availability in a mission critical application

large server: resilient/scalable server which ships as a pre-integrated/pre-tested system housed in one or more full frames or racks and that includes a high connectivity input/output subsystem with a minimum of 32 dedicated input/output slots.

managed server: computer server that is designed for a high level of availability in a highly managed environment

multi-node server: computer server that is designed with two or more independent server nodes that share a single enclosure and one or more power supplies and in which power is distributed to all nodes through shared power supplies

NOTE to entry: Server nodes in a multi-node server are not designed to be hot-swappable.

network server: large scale network device which contains the same components as a computer server together with more than 11 ports, has a total line rate throughput of greater than or equal to 12Gb/s and is designed to dynamically reconfigure ports and speed and to support a virtualized network environment, software defined networking

NOTE to entry: Supporting features are described by the product's datasheet description and is either accompanied with vendor specific utilities and/or commercially available software supporting these functions.

pedestal server: self-contained computer server that is designed with power supply units, cooling, input/output devices, and other resources necessary for stand-alone operation within a frame similar to that of a tower client computer.

rack-mounted server: computer server that is designed for deployment in a standard 19inch data centre rack as defined by EN 60297 [i.1].

NOTE to entry: For the purposes of this specification, a blade server is considered under a separate category and excluded from the rack-mounted category.

resilient server: computer server designed with extensive reliability, availability, serviceability (RAS) and scalability features integrated in the micro architecture of the system, central processing unit and chipset

NOTE to entry: The characteristics of a resilient server are described in the Annex B

server appliance: computer server that is bundled with a pre-installed operating system and application software which is used to perform a dedicated function or set of tightly coupled functions.

NOTE 1 to entry: Server appliances deliver services through one or more networks (e.g., Internet Protocol or Storage Area Network), and are typically managed through a web or command line interface.

NOTE 2 to entry: Server appliance hardware and software configurations are customized by the vendor to perform a specific task (e.g., name services, firewall services, authentication services, encryption services, and voice-over-IP services), and are not intended to execute user-supplied software.

controller system: computer or computer server that manages a benchmark evaluation process

data averaging interval: time period over which all samples captured by the high-speed sampling electronics of the power analyzer are averaged to provide the measurement set

hard disk drive: primary computer storage device which reads and writes to one or more rotating magnetic disk platters

High Performance Computing (HPC) System: computing system which is designed and optimized to execute highly parallel applications.

hypervisor: hardware virtualization technique that enables multiple guest operating systems to run on a single host system at the same time

Editors NOTE; Recommend changing to "an operating system level software that establishes and manages a virtualized environment which enables multiple operating systems to run on a single physical system at the same time"

idle state: operational state of a computer server in which the operating system and other software have completed loading, the computer server is capable of completing workload transactions, but no active workload transactions are requested or pending by the system (i.e., the computer server is operational, but not performing any useful work).

NOTE 1 to entry: For systems where ACPI standards are applicable, idle state correlates only to ACPI System Level S0.

network client (testing): computer or computer server that generates workload traffic for transmission to a unit under test connected via a network switch

network equipment: device whose primary function is to pass data among various network interfaces, providing data connectivity among connected devices (e.g. routers and switches) via the routing of data packets encapsulated according to Internet Protocol, Fibre Channel, InfiniBand or similar protocol

power supply unit: device that converts a.c. or d.c. input power to one or more d.c. power outputs for the purpose of powering a computer server.

a.c.-d.c power supply unit: power supply unit that converts line-voltage alternating current (a.c.) input power into one or more direct current (d.c.) power outputs for the purpose of powering a computer server

d.c.-d.c power supply unit: power supply unit that converts line-voltage direct current (d.c.) input power to one or more d.c. outputs for the purpose of powering a computer server

NOTE to entry: For purposes of this specification, a dc-dc converter (also known as a voltage regulator) that is internal to a computer server and is used to convert a low voltage dc (e.g. 12 V dc) into other dc power outputs for use by computer server components is not considered a dc-dc power supply

single output power supply unit: power supply unit designed to deliver the majority of its rated output power to one primary direct current (d.c.) output for the purpose of powering a computer server

multi-output power supply unit: power supply unit designed to deliver the majority of its rated output power to more than one primary direct current (d.c.) output for the purpose of powering a computer server

product category: second-order classification or sub-type within a product type that is based on product features and installed components and used in the present document to determine qualification and test requirements

reported maximum power: highest maximum power recorded on the twelve SERT worklet scores for the two tested configurations

server processor utilization: ratio of processor computing activity to full-load processor computing activity at a specified voltage and frequency, measured instantaneously or with a short term average of use over a set of active and/or idle cycles

server product family: high-level description for a group of servers sharing one chassis and motherboard combination that may contain more hardware and software configurations

solid state drive: storage device that uses memory chips instead of rotating magnetic platters for data storage.

storage product: fully-functional storage system that supplies data storage services to clients and devices attached directly or through a network

NOTE 1 to entry: A storage product may be composed of integrated storage controllers, storage devices, embedded network elements, software, and other devices. While storage products may contain one or more embedded processors, these processors do not execute user-supplied software applications but may execute data-specific applications (e.g., data replication, backup utilities, data compression, install agents).

NOTE 2 to entry: Components and subsystems that are an integral part of the storage product architecture (e.g., to provide internal communications between controllers and disks) are considered to be part of the storage product.

NOTE 3 to entry: Components that are normally associated with a storage environment at the data centre level (e.g. devices required for operation of an external SAN) are not considered to be part of the storage product.

storage server: enterprise storage device which contains the same components as a computer server together with ≥ 10 storage devices and software (vendor or 3rd party) that supports Storage System Connectivity, Capacity Optimization Management (COMs), virtualized storage environment and software defined storage

NOTE to entry: Supporting features are described by the product's datasheet description and is either accompanied with vendor specific utilities and/or commercially available software supporting these functions.

Uninterruptible Power Supply (UPS): combination of convertors, switches, and energy storage devices (such as batteries) constituting a power system for maintaining continuity of load power in case of input power failure

deployed power: xxxxx

efficiency: xxxxx

normalized performance: xxxxx

maximum power: xxxxx

4 Server product family configurations for testing

Editors NOTE: We want a consistent feasible testing method similar to Energy Star, but must be able to ship every different combination/ conditions that people purchase }

4.1 Typical configuration

4.2 "High-end" performance configuration

"High-end" performance configuration of a server product family means the combination of two solid state drives (SSDs), processor with the highest product of core count and frequency and memory capacity (in GB) equal to 1.0 to 2.0 times the product of the number of central processing units (CPUs), cores and hardware threads that represents the highest performance product model within the product family.

4.3 "Low-end" performance configuration

"Low-end" performance configuration of a server product family means the combination of two 10,000 rpm hard disk drives (HDDs), processor with the lowest product of core count and frequency and memory capacity (in GB) equal to 0.5 to 0.75 times the product of the number of CPUs, cores and hardware threads that represents the lowest performance product model within the product family.

5 Metrics

5.1 Active state metric

The SERT™ tool reports performance and power data for:

- 7 CPU worklets and of the 7 CPU worklets, 6 are used in the creation of the single value efficiency metric i.e. Compress, LU, CryptoAES, SOR, Sort, and SHA 256;

  NOTE: XML_validate is represented in the capacity metric and is therefore excluded from the CPU workload calculation.

- 2 memory worklets: Flood3 and Capacity3;
- 2 storage worklets: Sequential and Random;
- 1 hybrid worklet: Hybrid SSJ.

  NOTE: The Hybrid SSJ worklet is also considered as a CPU workload for the purposes of creating a single combined efficiency metric.

For each worklet, data is reported for a set of proportional performance intervals and associated, measured power values along with other test measurements. An interval efficiency value can be calculated by dividing each normalized performance value by the interval power value. The set of individually measured Performance and Power values with their associated efficiency value will be referred to as interval data.

In order to create a single energy efficiency metric for a server it is necessary to combine the worklet interval performance and power values for all the different worklets.

The method developed by the Green Grid SERT Analysis Working Group (WG) and the SPECpower Committee to create a single efficiency metric follows the following general procedure:

1) combine individual worklet normalized performance and power interval data to obtain an overall Efficiency, Performance and Power value for the worklet;
2) combine worklet Efficiency, Performance and Power values by workload type (CPU, Memory, Storage) to obtain a workload type value;
3) combine worklet types using a weighted geomean to obtain a single, total server Efficiency, Performance or Power value.

The geomean function offers the best option to combine the interval data to a worklet efficiency score and the workload (CPU, memory, storage) worklet efficiency scores to create a workload efficiency score. Using the geomean prevents any single performance, power, worklet or workload efficiency score from unduly influencing the single metric.

$$Eff_{server} = {Perf_{server}} \big/ {Pwr_{server}} \qquad \text{Equation 1}$$

Alternatively {choice depending on assessment}

$$Eff_{server} = \exp\left[W_{CPU} \times \ln\left(Eff_{CPU}\right) + W_{Memory} \times \ln\left(Eff_{Memory}\right) + W_{Storage} \times \ln\left(Eff_{Storage}\right)\right] \qquad \text{Equation 2}$$

$$Perf_{server} = \exp\left[W_{CPU} \times \ln\left(Perf_{CPU}\right) + W_{Memory} \times \ln\left(Perf_{Memory}\right) + W_{Storage} \times \ln\left(Perf_{Storage}\right)\right] \qquad \text{Equation 3}$$

$$Pwr_{server} = \exp\left[W_{CPU} \times \ln\left(Pwr_{CPU}\right) + W_{Memory} \times \ln\left(Pwr_{Memory}\right) + W_{Storage} \times \ln\left(Pwr_{Storage}\right)\right] \qquad \text{Equation 4}$$

where

W_{CPU} is the weighting assigned to the CPU worklets

= ???

W_{Memory} is the weighting assigned to the Memory worklets

= ???

$W_{Storage}$ is the weighting assigned to the Storage worklets

= ???

$$Eff_{worklet} = \left(\prod_{i=1}^{n} Eff_i\right)^{1/n} = {Perf_{worklet}} \big/ {Pwr_{worklet}} \qquad \text{Equation 5}$$

$$Perf_{worklet} = \left(\prod_{i=1}^{n} Perf_i\right)^{1/n} \qquad \text{Equation 6}$$

$$Pwr_{worklet} = \left(\prod_{i=1}^{n} Pwr_i\right)^{1/n} \qquad \text{Equation 7}$$

where

n = the number of worklet interval values for the worklet being evaluated

Eff_i = Efficiency value of the worklet interval i

$Perf_i$ = Performance value of worklet interval i

Pwr_i = Power value of the worklet interval i

Now that we have worklet Efficiency, Performance and Power values we combine these using a geomean in order to obtain a worklet type value.

$$Eff_{CPU} = \left(\prod_{i=1}^{7} Eff_i\right)^{1/7} \qquad \text{Equation 8}$$

Where

i = CPU efficiency worklet index (1 for worklet$_{Compress}$, 2 for worklet$_{LU}$, 3 for worklet$_{SOR}$, 4 for worklet$_{Crypto}$, 5 for worklet$_{Sort}$, 6 for worklet$_{SHA256}$ and 7 for worklet$_{Hybrid\ SSJ}$)

$$Eff_{Memory} = \left(\prod_{i=1}^{2} Eff_i\right)^{1/2} \qquad \text{Equation 9}$$

Where

i = memory efficiency worklet index (1 for worklet$_{Flood3}$ and 2 for worklet$_{Capacity3}$)

$$Eff_{Storage} = \left(\prod_{i=1}^{2} Eff_i \right)^{1/2}$$

Equation 10

where

i = storage efficiency worklet index (1 for worklet$_{Sequential}$ and 2 for worklet$_{Random}$)

$$Eff_{server} = \exp\left[W_{CPU} \times \ln\left(Eff_{CPU} \right) + W_{Memory} \times \ln\left(Eff_{Memory} \right) + W_{Storage} \times \ln\left(Eff_{Storage} \right) \right]$$

Equation 11 (2)

5.2 Idle state metric

Idle power is the alternating current (a.c.) power of the device with no activity after running the SERT worklets. Idle power is reported by SERT. Idle power of the system typically scales based on the features and performance added. When establishing minimum criteria for server idle power, additional power allocation shall be provided consistent with the performance and added features in the device.

6 Test setup

6.1 Input power

Editors NOTE: A single setup is preferred for internal power/active/idle

Input power shall be as specified in Table 1 and Table 2. The frequency for input power shall be as specified in Table 3.

Table 1 - Input power requirements for products with nameplate rated ≤ 1500 W

Product type	Supply voltage	Voltage tolerance (%)	Total harmonic distortion (%, max.)
Servers with a.c.-d.c. single-output PSUs	230 VAC or 115 VAC (see NOTE)	1,0	2,0
Servers with a.c.-d.c. multi-output PSUs	230 VAC or 115 VAC (see NOTE)		
Optional Testing Conditions for ac-dc (Japanese market)	100 VAC		
Three-phase servers (North American market)	208 VAC		
Three-phase servers (European market)	400 VAC		
DC powered	48 VDC		
High Voltage DC (see ETSI EN 300 132-3-1 [1])	260 - 400 VDC		
NOTE 230 V ac refers to the European market and 115 V ac refers to the North American market			

Table 2 - Input power requirements for products with nameplate rated > 1500 W

Product Type	Supply Voltage	Voltage tolerance (%)	Total harmonic distortion (%, max.)
Servers with a.c.-d.c. single-output PSUs	230 VAC or 115 VAC (see NOTE)	4,0	5,0
Servers with a.c.-d.c. multi-output PSUs	230 VAC or 115 VAC (see NOTE)		
Optional Testing Conditions for ac-dc (Japanese mrket)	100 VAC		
Three-phase servers (North American market)	208 VAC		
Three-phase servers (European market)	400 VAC		
DC powered	48 VDC		
High Voltage DC (see ETSI EN 300 132-3-1 [1])	260 - 400 VDC		
NOTE 230 V ac refers to the European market and 115 V ac refers to the North American market			

Table 3 - Input frequency requirements for all products

Supply voltage	Frequency	Frequency tolerance
100 VAC	50 Hz or 60 Hz	1,0
115 VAC	60 Hz	
230 VAC	50 Hz or 60 Hz	
Three-phase (North American Market)	60 Hz	
Three-phase (European Market)	50 Hz	

Reference: https://plugloadsolutions.com

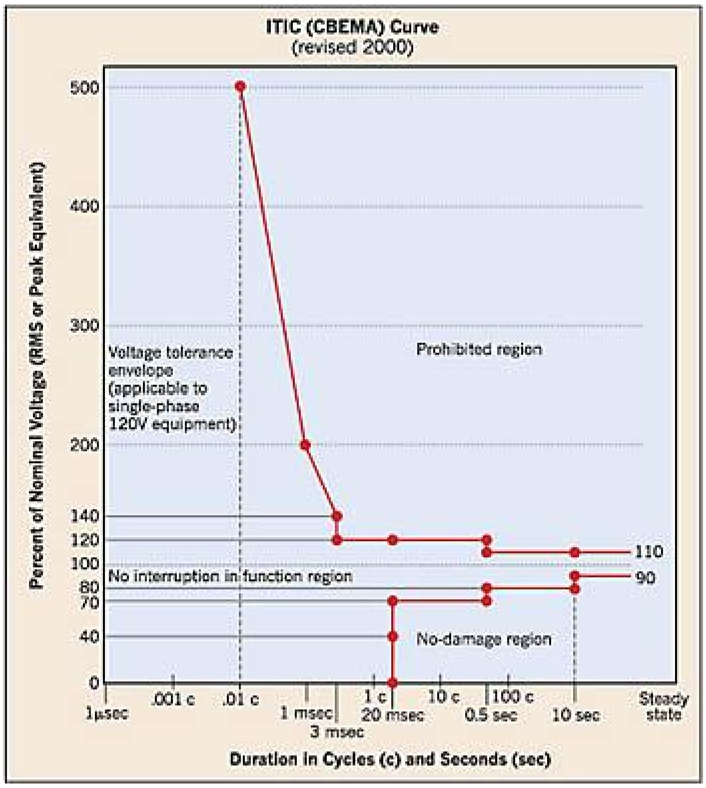

Figure 1- ITIC (CBEMA) curve (as published in IEEE Standard 1100: 1999 [i.4])

6.2 Environmental conditions

6.2.1 Ambient Temperature:

Ambient temperature shall be within 25 ± 5 °C.

Editor NOTE: reference required to measurement conditions - EN 300 019 [i.2]? to be discussed following the outcome of the Consultation Forum

6.2.2 Relative Humidity:

Relative humidity shall be within 15% and 80%.

Editor NOTE: reference required to measurement conditions - EN 300 019 [i.2]? to be discussed following the outcome of the Consultation Forum

6.3 Power analyser

The power analyzer shall report true Root Mean Square (RMS) power and at least two of the following parameters: voltage, current, and power factor.

The power analyzer shall:

a) be chosen from the list of power measuring devices specified in the most current SERT Design Document [3] ;

b) have been calibrated within a year of the test date, by a standard traceable to the National Institute of Science and Technology (USA) or a counterpart national metrology institute in other countries.

c) feature an available current crest factor of 3 or more at its rated range value;

d) for power analyzers that do not specify the current crest factor, the power analyzer shall be capable of measuring an amperage spike of at least 3 times the maximum amperage measured during any 1 second sample;

e) have a minimum frequency response of 3,0 kHz;

f) have a minimum resolution of:

- 0,01 W for measurement values less than 10 W;
- 0,1 W for measurement values from 10 W to 100 W; and
- 1,0 W for measurement values greater than 100 W.

g) have a power measurement accuracy of no greater than 1,0 %;

h) have a logging performance of:

- minimum reading rate: one set of measurements (power measurement in W) per second;
- data averaging interval equal to the reading rate

6.4 Temperature sensor

The temperature sensor shall:

a) be chosen from the list of temperature measuring devices specified in the most current SERT Design Document [3];

b) have a temperature measurement accuracy of no greater than ± 0.5 °C when measured no more than 50mm in front of (upwind of) the main airflow inlet of the Unit Under Test (UUT).

c) have a logging performance of minimum reading rate: four samples per minute.

6.5 Active state test tool

The active state test tool shall be that specified in the most current version of SERT, provided by the Standards Performance Evaluation Corporation (SPEC) [5].

6.6 Controller system

The Controller System may be a Server, a desktop computer, or a laptop and shall be used to record power from the equipment specified in 6.3and temperature data from the equipment specified in 6.4.

The Controller System and the UUT shall be connected to each other via an Ethernet network switch.

6.7 General SERT requirements

Any additional requirements specified in any SPEC, or the most current SERT supporting documents shall be followed, unless otherwise specified in this test method.

Supporting documents from SPEC include:

a) SPEC Power and Performance Methodology;

7 Unit Under Test

7.1 Configuration

The configuration of the UUT shall be as specified in Table 4.

Table 4 - Configuration of UUT

A)	As-shipped Condition	Products shall be tested in their “as-shipped” configuration, which includes both hardware configuration and system settings, unless otherwise specified in this test method. Where relevant, all software options shall be set to their default condition.
B)	Measurement location	All power measurements shall be taken at a point between the a.c. power source and the UUT Uninterruptible Power Supply (UPS) units shall not be connected between the power meter and the UUT. The power meter shall remain in place until all Idle and Active State power data are fully recorded. When testing a blade system, power shall be measured at the input of the blade chassis (i.e. at the power supplies that convert data centre distribution power to chassis distribution power).
C)	Air flow	Purposefully directing air in the vicinity of the measured equipment in a way that would be inconsistent with normal data centre practices is prohibited
D)	Power supplies	All PSUs shall be connected and operational. For UUT with multiple PSUs: - all power supplies shall be connected to the a.c. power source and operational during the test; - if necessary, a Power Distribution Unit (PDU) may be used to connect multiple power supplies to a single source (if a PDU is used, any overhead electrical use from the PDU shall be included in the power measurement of the UUT). For blade servers with half-populated chassis configurations, the power supplies for the unpopulated power domains can be disconnected (Table 5, D) for more information)
E)	Power Management and Operating System	The as-shipped operating system or a representative operating system shall be installed. Products that are shipped without operating systems shall be tested with any compatible operating system installed. For all tests, the power management techniques and/or power saving features shall be left as-shipped. Any power management features which require the presence of an operating system (i.e. those that are not explicitly controlled by the Basic Input Output System (BIOS) or management controller) shall be tested using only those power management features enabled by the operating system by default.
F)	Storage	Products shall be tested for qualification with at least one HDD or one SSD installed. Products that do not include pre-installed hard drives (HDD or SSD) shall be tested using a storage configuration used in an identical model for sale that does include preinstalled hard drives. Products that do not support installation of hard drives (HDD or SSD) and, instead, rely exclusively on external storage solutions (e.g. storage area network) shall be tested using external storage solutions.
G)	Blade System and Dual/Multi-Node Servers	A blade system or dual/multi-node server shall have identical configurations for each node or blade server including all hardware components and software/power management settings. These systems shall also be measured in a way that ensures all power from all tested nodes/blade servers is captured by the power meter during the entire test.
H)	Blade Chassis	The blade chassis, at a minimum, shall have power, cooling, and networking capabilities for all the blade servers. The blade chassis shall be populated as specified in Table 5, D). All power measurements for blade systems shall be made at the input of the blade chassis.
I)	BIOS and UUT System Settings	All BIOS settings shall remain as-shipped unless otherwise specified in the test method

J)	Input/Output (I/O) and Network Connection	The UUT shall have at least one port connected to an Ethernet network switch. The switch shall be capable of supporting the UUT's highest and lowest rated network speeds. The network connection shall be live during all tests, and, although the link shall be ready and able to transmit packets, no specific traffic is required over the connection during testing. For the purpose of testing ensure the UUT offers at least one Ethernet port (using a single add-in card only if no onboard Ethernet support is offered).
K)	Energy Efficient Ethernet	Products shipped with support for Energy Efficient Ethernet (compliant with IEEE 802.3az) shall be connected only to Energy Efficient Ethernet compliant network equipment during testing. Appropriate measures shall be taken to enable EEE features on both ends of the network link during all tests.

7.2 Test procedure

The UUT test configuration shall be in accordance with Table 5.

Table 5 - Test configuration of UUT

A)	The UUT shall be tested with the processor sockets populated.
B)	The UUT shall be installed in a test rack or location and shall not be physically moved until testing is complete.
C)	For a multi-node system, the UUT shall be tested for per node power consumption in the fully-populated blade chassis configuration. All multi-node servers installed in the blade chassis shall be identical, sharing the same configuration.
D)	For a blade system, the UUT shall be tested for blade server power consumption in the half-populated blade chassis configuration with an additional option of testing the UUT in the fully populated blade chassis configuration. For blade systems, populate the blade chassis as follows: 1. Individual blade server configuration All blade servers installed in the blade chassis shall be identical, sharing the same configuration (homogeneous). 2. Half -chassis population (Required) The number of blade servers required to populate half the number of single-wide blade server slots available in the blade chassis shall be calulated. For blade chassis having multiple power domains, the number of power domains shall be chosen that is closest to filling half of the blade chassis. In a case where there are two choices that are equally close to filling half of the blade chassis, test with the domain or combination of domains which utilize a higher number of blade servers. Example 1: A blade chassis supports up to 7 single-wide blade servers on two power domains. One power domain supports 3 blade servers and the other supports 4 blade servers. In this example, the power domain which supports 4 blade servers would be fully populated during testing, while the other power domain would remain unpopulated. Example 2: A blade chassis supports up to 16 single-wide blade servers on four power domains. Each of the four power domains supports 4 blade servers. In this example, two of the power domains would be fully populated during testing, while the other two power domains would remain unpopulated. All user manual or manufacturer recommendations shall be followed for partially populating the blade chassis, which may include disconnecting some of the power supplies and cooling fans for the unpopulated power domains. If user manual recommendations are not available or are incomplete, then use the following guidance: Completely populate the power domains. If possible, disconnect the power supplies and cooling fans for unpopulated power domains. Fill all empty bays with blanking panels or an equivalent airflow restriction for the duration of testing. 3. Full-chassis population (Optional) Populate all available blade chassis bays. All power supplies and cooling fans shall be connected. Proceed with all required tests in the test procedure as specified in Section 6?
E)	The UUT shall be connected to a live Ethernet (IEEE 802.3) network switch. The live connection shall be maintained for the duration of testing, except for brief lapses necessary for transitioning between link speeds.
F)	The Controller System required to provide SERT workload harness control, data acquisition, or other UUT testing support shall be connected to the same network switch as the UUT and satisfy all other UUT network requirements. Both the UUT and Controller System shall be configured to communicate via the network.

G)	The power meter shall be connected to an ac voltage source set to the appropriate voltage and frequency for the test, as specified in Section 4.
H)	The UUT shall be connected to the measurement power outlet on the power meter following the guidelines in Table 4, B).
I)	The data output interface of the power meter and the temperature sensor shall be connected to the appropriate inputs of the Controller System.
J)	It shall be verified that the UUT is configured in its as–shipped configuration.
K)	It shall be verified that the Controller System and UUT are connected on the same internal network via an Ethernet network switch.
L)	Using a normal ping command, It shall be verified that the Controller System and UUT can communicate with each other.
M)	The most current SERT [4] shall be installed on the UUT and the Controller System as specified in the most current SERT User Guide [4]

8 Measurement

8.1 Measurement for active state

The measurement shall be in accordance with Table 6.

Table 6 - Measurement of active state

A)	The UUT shall be re-booted.
B)	Between 5 and 15 minutes after the completion of initial boot or log in, the most current SERT User Guide [4] shall be followed to engage SERT
C)	All steps outlined in the most current SERT User Guide [4] shall be followed to successfully run SERT There shall be no manual intervention or optimization of the Controller System, UUT, or its internal and external environment during the execution of SERT.
D)	Once SERT is completed, the following output files shall be included with all testing results: 1. Results.xml 2. Results.html 3. Results.txt 4. All results-chart png files (e.g. results-chart0.png, results-chart1.png, etc.) 5. Results-details.html 6. Results-details.txt 7. All results-details-chart png files (e.g. results-details-chart0.png, results-details-chart1.png, etc.)

8.2 Measurement for idle state

The measurement shall be in accordance with Table 7.

Table 7 - Measurement of idle state

A)	The UUT shall be powered-on, either by switching it on or connecting it to mains power.
B)	The Controller System shall eb powered-on.
C)	Begin recording elapsed time.
D)	Between 5 and 15 minutes after the completion of initial boot or log in, set the power meter to begin accumulating idle power values at an interval of greater than or equal to 1 reading per second.
E)	Accumulate idle power values for 30 minutes. The UUT shall maintain in Idle State throughout this period and shall not enter lower power states with limited functionality (e.g., sleep or hibernate).
F)	Record the average idle power (arithmetic mean) during the 30 minute test period.
G)	Between 5 and 15 minutes after the completion of initial boot or log in, set the power meter to begin accumulating idle power

	values at an interval of greater than or equal to 1 reading per second.
H)	When testing a multi-node or blade system, proceed as follows to derive single node or single blade server power: 1. divide the measured total idle power in Section 6.1.F) by the number of nodes/Blade Servers installed for the test; 2. record the measured total and per-node/per-blade server power values as calculated in 6.1.G)1) for each measurement.

Editors NOTE: Market surveillance will check if the determined value shall not exceed the declared value by more than 10 %.

8.3 Measurement for power supply

8.3.1 Measurement for internal power supply

The measurement shall be in accordance with Table 7.

Table 8 - Measurement of internal power supply

A)	For all types of internal power supplies, the efficiency and the power factor shall be measured at 10%, 20 %, 50 % and 100 % of the rated [nameplate] output power
B)	For single-output internal power supplies, the efficiency shall also be measured at 10 % of the rated [nameplate] output power
C)	For single-output internal power supplies with a rated output power greater than 500 W, the power factor shall also be measured at 10 % of the rated [nameplate] output power.
D)	Test setup, test conditions, and measurement instrument specifications shall comply with clause 6.3.
E)	This test procedure assumes that the internal power supply meets following criteria: Detailed input and output ratings are available on the name plate or in manufacturer's literature, specifying the maximum loads that can safely be placed on each individual dc output voltage bus and, where necessary, groupings of those voltage busses. The power supply has connectors that allow the d.c. output voltage busses to be connected and disconnected from the powered product non-destructively. The power supply can be easily detached from the housing of the product it powers, without causing harm to other circuits and components of the product.
F)	The power supply can be easily detached from the housing of the product it powers, without causing harm to other circuits and components of the product.
G)	In the event the above criteria are not met, a test board (see Measurement for test board power supply) shall be provided to enable testing.
NOTE 1: Such data could already be available from the manufacturer of the power supply; in such cases, the manufacturer could decide to use them. However, where 3rd party test results are used, it is the responsibility of the manufacturer to assess the trustworthiness of the sources. NOTE 2: The EPRI/ECOVA Generalized Test Protocol [i.3] is an acceptable basis for providing the required data.	

8.3.2 Measurement for test board power supply

8.3.2.1 General

Tests specified in this section shall be made on the power supply of the computer under test, after it has been disconnected from the powered parts and extracted from the housing. Alternatively, another unit, representative of the built-in power supply may be used.

8.3.2.2 Test loads

Active loads such as electronic loads or passive loads such as rheostats may be used as dc test loads. They shall be able to maintain the required current loading set point for each output voltage within an accuracy of ± 0.5%.

8.3.2.3 Test leads and wiring

Appropriate wires shall be used to avoid excessive overheating and reduce voltage drop across the wires. If measurements are not taken directly at the connector pins, voltage drop against the additional wires shall be taken into account.

NOTE: If applicable, voltage drop across the input wires will be subtracted from the measured input voltage, and the voltage drop across the output wires will be added the measured input voltage for the measurement of power efficiency.

8.3.2.4 Warm up time

Whereas internal temperature of the components could impact its efficiency, the power supply under test shall be loaded up to the test load a period of at least 15 minutes or until the reading over two consecutive five-minute intervals does not change by more than ± 0.2%.

8.3.2.5 Power measurements

The true RMS wattmeter used to carry out a.c. input power measurements shall meet the requirements of clauses 5.7 and 5.8 of EN 62623:2013 [1]. Input power shall be determined using an averaging technique over a minimum of 32 input cycles utilizing the measurement instrument averaging function.

For appliances connected to more than one phase, the power measurement instrument shall be equipped to measure the total power of all phases connected.

d.c. output power measurements shall be made with a suitably calibrated voltmeter and ammeter.

8.3.2.6 Power Factor (PF) measurement

In order to avoid interaction between the a.c. power source and a possible Power Factor Correction (PFC) circuit, a Line Impedance Stabilization Network (LISN) shall be inserted in series between the power source and the a.c. input of the power supply under test.

Editors NOTE: Market surveillance will check if the determined value of the PSU efficiency shall not be lower than the declared value by more than 2 % and that the power factor shall not be lower than the declared value by more than 10%.

9 Measurement report

Editors NOTE: What will be listed?

Annex A: Example of a report (informative)

Annex B: Additional definitions (normative)

B.1 Equipment requirements

In the present document, the items listed in Table B.1 shall meet the requirements listed.

Table B.1 - Item requirements

Item	For purposes of this specification, the item must meet all of the listed criteria:
Computer server	is marketed and sold as a Computer Server
	Is designed for and listed as supporting one or more computer server operating systems (OS) and/or hypervisors
	is targeted to run user-installed applications typically, but not exclusively, enterprise in nature
	provides support for error-correcting code (ECC) and/or buffered memory (including both buffered dual in-line memory modules DIMMs) and buffered on board (BOB) configurations)
	is packaged and sold with one or more ac-dc or dc-dc power supplies
	is designed such that all processors have access to shared system memory and are visible to a single OS or hypervisor
Managed server	is designed to be configured with redundant power supplies
	contains an installed dedicated management controller (e.g., service processor).
HPC system	Marketed and sold as a computer server optimized for higher performance computing applications;
	Designed (or assembled) and optimized to execute highly parallel applications;
	Consist of a number of typically homogeneous computing nodes, clustered primarily to increase computational capability;
	Includes high speed inter-processing interconnections between nodes.
Controller system	A. start and stop each segment (phase) of the performance benchmark
	control the workload demands of the performance benchmark;
	start and stop data collection from the power analyzer so that power and performance data from each phase can be correlated
	store log files containing benchmark power and performance information
	convert raw data into a suitable format for benchmark reporting, submission and validation
	collect and store environmental data, if automated for the benchmark.
RAS features	
Server product family configuration	be from the same model line or machine type;
	either share the same form factor (i.e., rack-mounted, blade, pedestal) or share the same mechanical and electrical designs with only superficial mechanical differences to enable a design to support multiple form factors;
	either share processors from a single defined processor series or share processors that plug into a common socket type;
	share the power supply unit(s).

B.2 Components of computer servers

Table B.2 provides details of component of a computer server.

Table B.2 - Item requirements

I/O Device	A device which provides data input and output capability between a computer server and other devices. An I/O device may be integral to the computer server motherboard or may be connected to the motherboard via expansion slots (e.g., PCI, PCIe). Examples of I/O devices include discrete Ethernet devices, InfiniBand devices, RAID/SAS controllers, and Fibre Channel devices.
I/O Port	Physical circuitry within an I/O device where an independent I/O session can be established. A port is not the same as a connector receptacle; it is possible that a single connector receptacle can service multiple ports of the same interface
Motherboard	The main circuit board of the server. For purposes of this specification, the motherboard includes connectors for attaching additional boards and typically includes the following components: processor, memory, BIOS, and expansion slots

Processor	The logic circuitry that responds to and processes the basic instructions that drive a server. For purposes of this specification, the processor is the central processing unit (CPU) of the computer server
Memory	For purposes of this specification, memory is a part of a server external to the processor in which information is stored for immediate use by the processor
Power Supply Unit (PSU)	A computer server PSU must be self-contained and physically separable from the motherboard and must connect to the system via a removable or hard-wired electrical connection.
Single-output PSU	Single-output PSUs may offer one or more standby outputs that remain active whenever connected to an input power source. For purposes of this specification, the total rated power output from any additional PSU outputs that are not primary and standby outputs shall be no greater than 20 watts. PSUs that offer multiple outputs at the same voltage as the primary output are considered single-output PSUs unless those outputs (1) are generated from separate converters or have separate output rectification stages, or (2) have independent current limits.
Multi-output PSU	Multi-output PSUs may offer one or more standby outputs that remain active whenever connected to an input power source. For purposes of this specification, the total rated power output from any additional PSU outputs that are not primary and standby outputs is greater than or equal to 20 watts.

B.3 Identifying resilient server class

Reliability Features: Features that support a server's ability to perform its intended function without interruption due to component failures (e.g., component selection, temperature and/or voltage de-rating, error detection and correction).
Availability Features: Features that support a server's ability to maximize operation at normal capacity for a given duration of downtime (e.g., redundancy [both at micro- and macro-level]).
Serviceability Features: Features that support a server's ability to be serviced without interrupting operation of the server (e.g., hot plugging).

In order to classify as a resilient server all of the features listed in Table B.3 shall be provided.

Table B.3 - RAS requirements

A)	Processor RAS and Scalability
A.1	Processor RAS: The processor must have capabilities to detect, correct, and contain data errors, as described by all of the following: Error detection on L1 caches, directories and address translation buffers using parity protection; Single bit error correction (or better) using ECC on caches that can contain modified data. Corrected data is delivered to the recipient (i.e., error correction is not used just for background scrubbing); Error recovery and containment by means of (1) processor checkpoint retry and recovery, (2) data poison indication (tagging) and propagation, or (3) both. The mechanisms notify the OS or hypervisor to contain the error within a process or partition, thereby reducing the need for system reboots; and (1) Capable of autonomous error mitigation actions within processor hardware, such as disabling of the failing portions of a cache, (2) support for predictive failure analysis by notifying the OS, hypervisor, or service processor of the location and/or root cause of errors, or (3) both.
A.2	The processor technology used in resilient and scalable servers is designed to provide additional capability and functionality without additional chipsets, enabling them to be designed into systems with 4 or more processor sockets. The processors have additional infrastructure to support extra, built-in processor busses to support the demand of larger systems.
A.3	The server provides high bandwidth I/O interfaces for connecting to external I/O expansion devices or remote I/O without reducing the number of processor sockets that can be connected together. These may be proprietary interfaces or standard interfaces such as PCIe. The high performance I/O controller to support these slots may be embedded within the main processor socket or on the system board.
B	**Memory RAS and Scalability**
B.1	Provides memory fault detection and recovery through Extended ECC
B.2	In x4 DIMMs, recovery from failure of two adjacent chips in the same rank;
B.3	Memory migration: Failing memory can be proactively de-allocated and data migrated to available memory. This can be implemented at the granularity of DIMMs or logical memory blocks. Alternatively, memory can also be mirrored;
B.4	Uses memory buffers for connection of higher speed processor -memory links to DIMMs attached to lower speed DDR channels. Memory buffer can be a separate, standalone buffer chip which is integrated on the system board, or integrated on

	custom-built memory cards. The use of the buffer chip is required for extended DIMM support; they allow larger memory capacity due to support for larger capacity DIMMs, more DIMM slots per memory channel, and higher memory bandwidth per memory channel than direct-attached DIMMs. The memory modules may also be custombuilt, with the memory buffers and DRAM chips integrated on the same card;
B.5	Uses resilient links between processors and memory buffers with mechanisms to recover from transient errors on the link; and
B.6	Lane sparing in the processor-memory links. One or more spare lanes are available for lane failover in the event of permanent error.
C.	**Power Supply RAS**
	All PSUs installed or shipped with the server shall be redundant and concurrently maintainable. The redundant and repairable components may also be housed within a single physical power supply, but must be repairable without requiring the system to be powered down. Support must be present to operate the system in degraded mode when power delivery capability is degraded due to failures in the power supplies or input power loss
D.	**Thermal and Cooling RAS**
	All active cooling components, such as fans or water-based cooling, shall be redundant and concurrently maintainable. The processor complex must have mechanisms to allow it to be throttled under thermal emergencies. Support must be present to operate the system in degraded mode when thermal emergencies are detected in system components..

In order to classify as a resilient server at least six of the features listed in Table B.4 shall be provided.

Table B.4 - System resiliency requirements

E.	**System Resiliency**
E.1	Support of redundant storage controllers or redundant path to external storage;
E.2	Redundant service processors;
E.3	Redundant dc-dc regulator stages after the power supply outputs
E.4	The server hardware supports runtime processor de-allocation;
E.5	I/O adapters or hard drives are hot-swappable;
E.6	Provides end to end bus error retry on processor to memory or processor to processor interconnects;
E.7	Supports on-line expansion/retraction of hardware resources without the need for operating system reboot (“on-demand” features);
E.8	Processor Socket migration: With hypervisor and/or OS assistance, tasks executing on a processor socket can be migrated to another processor socket without the need for the system to be restarted;
E.9	Memory patrol or background scrubbing is enabled for proactive detection and correction of errors to reduce the likelihood of uncorrectable errors; and
E.10	Internal storage resiliency: Resilient systems have some form of RAID hardware in the base configuration, either through support on the system board or a dedicated slot for a RAID controller card for support of the server’s internal drives. F. System Scalability – All of the following shall be present in the server:
E.11	Higher memory capacity: >=8 DDR3 or DDR4 DIMM Ports per socket, with resilient links between the processor socket and memory buffers; and
E.12	Greater I/O expandability: Larger base I/O infrastructure and support a higher number of I/O slots. Provide at least 32 dedicated PCIe Gen 2 lanes or equivalent I/O bandwidth, with at least one x16 slot or other dedicated interface to support external PCIe, proprietary I/O interface or other industry standard I/O interface

C.2 Scaling of idle power limits

Memory, drives, additional features and increased performance capacity

Annex D: Deployed Power Assessment

D.1 Overview of the Deployed Power Analysis Methodology for validation of a proposed server efficiency metric

In order to evaluate potential metrics, a series of assessments to the relative power impact of selecting the server offers a definitive confirmation of a metric's ability to predict efficiency of the server as deployed in the data centre. The assessment comprises a graphical correlation and rank comparison between the power impact of a number of servers deployed to execute a defined workload versus the aggregated efficiency metric for the server. The selection of servers mimics the provisioning method used by IT professionals when determining the data processing needs of that data centre.

The Deployed Power assessment is based on determining the ability of provisioning a set of servers for a targeted workload that results in a minimum expenditure of energy at the data centre, across the various utilization levels. The metric validation is to ensure that a better efficiency score will result in a lower deployed server power demand to execute that work in a data centre. The use of a deployed power calculation enables differentiation between the effectiveness of a low performance, low power server and a high performance, high power server, as it enables an assessment of the number of servers and their associated energy use required to deliver a given workload in a data centre or office environment.

To calculate the number of servers needed to perform a workload and their associated deployed power, it is necessary to select a workload level to use to calculate the number of deployed servers.

1) Target workload should represent the maximum composite of the work targeted for the data centre. Based on actual workloads deployed in data centres, the weights used are 65% CPU, 30% Memory and 5%Storage.

2) A value of 100 * the maximum performance value of the group of tested servers defines the target workload performance level for the evaluation. This value is large enough avoid quantization effects.

3) As servers execute a diverse range of workloads, three assessment workloads were selected: a CPU intensive workload, a memory intensive workload and a weighted workload which mimics the workload weighting of the combined metric being assessed.

4) Additionally, the following power/utilization/workload types to be used in our comparison analysis. The intent is to assess a combination of workload types and power consumption levels that a set of servers will experience in an operating environment:
   a) idle power as measured by the SERT tool;
   b) geomean of the power for all workloads at the 25% utilization (light workload);
   c) geomean of the power for all workloads at the 50% utilization (medium workload);
   d) geomean of the power for all workloads at the 100% utilization (heavy workload);
   e) weighted deployed power using the metric weighting;
   f) weighted deployed power using the CPU intensive workload weightings (85% CPU, 15% memory);
   g) weighted deployed power using the Memory intensive workload weightings (40% CPU, 60% memory).

   Multiple workloads and power use scenarios were assessed to validate that the combined metric is balanced and representative of efficiency across the range of workloads that servers are expected to perform and to avoid the assertion that use of a single power/workload/utilization might be biased to a particular outcome.

D.2 Determining the number of deployed servers

D.2.1 General

Any attempt at a single efficiency metric based upon the SERT tool must use some method to combine the individual worklet values to create a single value. The aggregation used to determine a single value is with the geomean combinatory method and the designated component (CPU, memory and storage) weightings to calculate the number of servers required.

In order to determine the number of servers required for any given server model one must determine both a performance target for the dataset and a performance capability for each individual server. The individual worklet performance values reported in the SERT tool are combined to determine the number of servers required to meet the performance target.

D.2.1 Establishing target performance

In order to minimize quantization issues, since deployed power is based on an integral number of servers, a 100 times the maximum performance of the highest performance server in the data set for the performance target,

The number of servers required to meet a desired performance level is calculated according to Equation B.1.

$$Deployed_{QTY_n} = Roundup\left(\frac{100 \times Max\left(Perf_{AllServers}\right)}{Perf_n}\right) \qquad \text{Equation D.1}$$

where:

$Perfmax_{AllServers}$ = the performance values for all servers in the data set
$Perfmax_n$= the maximum performance of server n.

D.2.1 Weighting factors

A weighted geomean (CPU 60 %: Memory 35 %: Storage 5 %) of performance, designated as the weighted performance maximum, is used.

Equation D.2 aggregates the geomean of the normalized maximum performance values to obtain a single maximum performance number for each individual server. The weighted maximum performance number represents the maximum capability of the server and what would be used to provision a data centre.

$$Perfmax_{weighted} = \exp\left[0,6 \times \ln\left(Perfmax_{CPU}\right) + 0,35 \times \ln\left(Perfmax_{Memory}\right) + 0,05 \times \ln\left(Perfmax_{Storage}\right)\right] \qquad \text{Equation D.2}$$

where:

$$Perfmax_{CPU} = \left(\prod_{i=1}^{7} Perfmax_i\right)^{1/7} \qquad \text{Equation D.3}$$

where i the CPU efficiency worklet and is for $\text{worklet}_{Compress}$, 2 for worklet_{LU}, 3 for worklet_{SOR}, 4 for worklet_{Crypto}, 5 for worklet_{Sort}, 6 for worklet_{SHA256} and 7 for $\text{worklet}_{Hybrid\ SSJ}$

$$Perfmax_{Memory} = \left(\prod_{i=1}^{2} Perfmax_i\right)^{1/2} \qquad \text{Equation D.4}$$

where i the memory efficiency worklet and is 1 for worklet_{Flood3} and 2 for $\text{worklet}_{Capacity3}$

$$Perfmax_{Storage} = \left(\prod_{i=1}^{2} Perfmax_i\right)^{1/2} \qquad \text{Equation D.5}$$

where i the storage efficiency worklet and is 1 for $\text{worklet}_{Sequential}$ and 2 for worklet_{Random}

$\text{Perfmax}_{\text{worklet}}$ represents the maximum performance score from the SERT data base.

$\text{Perfmax}_{\text{Wght}}$ represents the newly calculated weighted maximum performance
